Stock Module Model layer started	Sayfa No: 6

Today, I started working on the Model layer for the reporting screens in the Stock module. First, I studied the CodeIgniter 4 documentation in detail, focusing on the Model structure and the Query Builder class. During this research, I concentrated on the following topics:

- How Model files are organized within the framework,
- How to write dynamic queries using the Query Builder class,
- How functions like SUM, COUNT, and GROUP BY can be used for reporting purposes,
- Filtering methods such as where(), like(), groupStart()/groupEnd().

I also examined the existing database tables, specifically invoice (incoming) and delivery (outgoing), to identify which fields would be used in the reports.

The goal for today was to understand the infrastructure of the Model layer and plan its structure. Therefore:

- I created the ReportModel.php file and prepared the initial draft,
- I planned which parameters each function would receive and the type of data it would return.

At this stage, I have initiated the development of the Model layer.

```php
class StockReportModel extends Model
{
    2 usages
    public function getSummary(array $filters): array
    {
        return [];
    }

    2 usages
    public function getMovements(array $filters): array
    {
        return [];
    }

    1 usage
    public function exportExcel(array $filters): string
    {
        return '';
    }
}
```
