Clothes Module Controller Completed and Model Layer Preparation	Sayfa No: 12

Today, I continued working on the **Controller layer** of the reporting screens in the **Clothes module** and then began preparations for the **Model layer**.

The previous day, I had created the Controller file and planned the responsibilities of the functions. Today, I continued coding these functions:

- **index() method:** Implemented and made fully functional. It loads the reporting screen, displaying the filter form and an empty table skeleton to the user.
- **summaryReport() method:** Coded to validate filter parameters from the user (date, product, size, gender, unit, personnel) in the Controller and then pass them to the Model.
- **detailReport() method:** Prepared the basic skeleton. It is designed to fetch delivery date, personnel information, product, and size details from the Model and send them to the View in the future.

In the Controller, I focused on validating filter parameters (checking if the date range is empty or if a product has been selected) to prevent queries with invalid inputs. Initial tests using my sample dataset showed that the Controller works correctly.

In the second half of the day, I started preparations for the Model layer. I revisited CodeIgniter 4 documentation regarding Model definitions and Query Builder usage. Additionally, I analyzed the clothes and clothes_delivery tables to determine which tables would be used for reporting in the Clothes module. I observed that these tables contain product definitions and clothing assignments to personnel.With this, I planned the necessary Model infrastructure. Starting from the next day, I aim to implement the Model for the Clothes module and create the summary and detail report functions.

```php
public function index()
{
    return view( name: 'Internal/Clothes/Report/index');
}
public function filter()
{
    $filters = [
        'date_from' => $this->request->getPost('date_from'),
        'date_to'   => $this->request->getPost('date_to'),
        'item_id'   => (int) $this->request->getPost('item_id'),
        'size'      => $this->request->getPost('size'),
        'unit'      => $this->request->getPost('unit'),
        'gender'    => $this->request->getPost('gender'),
        'staff_id'  => (int) $this->request->getPost('staff_id'),
    ];

    return $this->response->setJSON([
        'ok'      => true,
        'summary' => $this->report->getSummary($filters),
        'detail'  => $this->report->getDetail($filters),
    ]);
}
```
